

Name: - Ayush Pandey

Batch: - Az-900 + Az-104

Assignment 07: - Network Watcher

- **What is Next Hop?**

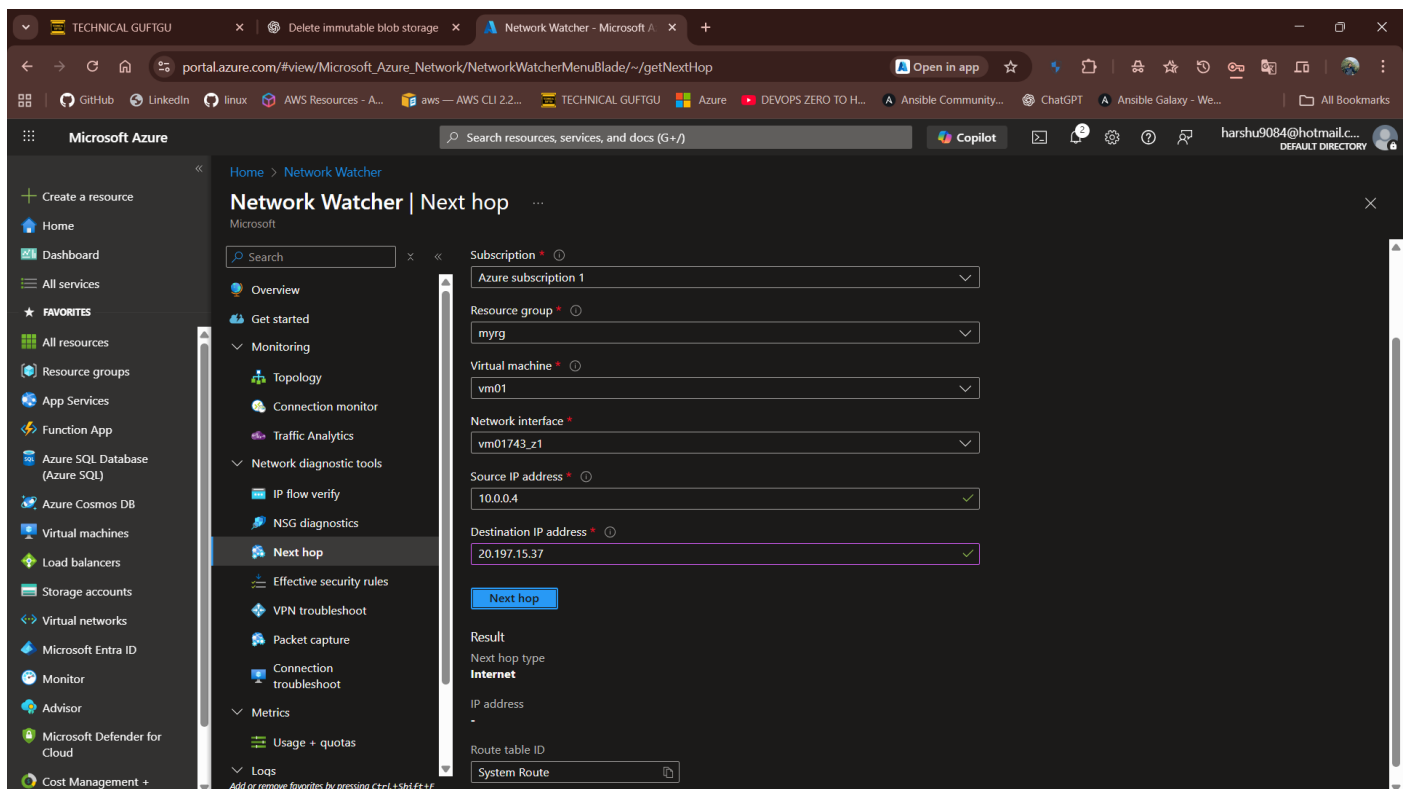

In Azure, a **Next Hop** means **the next stop (destination)** your network traffic takes **to reach its final target**.

When data travels from one virtual machine (VM) or subnet to another, Azure needs to decide **where to send that traffic next** — this is what **Next Hop** tells you.

👉 **Example:**

If VM1 wants to talk to VM2, Azure looks at the **route table** and says:

“The next hop is the virtual network” — meaning traffic goes directly inside the same VNet.

Or, if traffic is meant for the internet:

“The next hop is the Internet gateway.”

So, **Next Hop** = **the next network device or path Azure uses to forward packets**.

Each route in Azure has **two main parts**:

1. **Address prefix** (destination network)
2. **Next hop type** (where to send the packet next)

- **What is Effective Security Rule?**

Effective Security Rules in Azure mean the **final list of network security rules** that actually apply to a **network interface (NIC)** or **virtual machine (VM)** — after combining all the rules from **Network Security Groups (NSGs)** attached to the subnet and the VM.

👉 Think of it like this:

Your VM can have **two sets of security rules** —

1. One from the **subnet's NSG**
2. One from the **VM's (NIC's) NSG**

Azure looks at **both** and combines them to figure out:

“What traffic is really allowed or denied for this VM?”

That **combined result** is called the **Effective Security Rules**.

Example

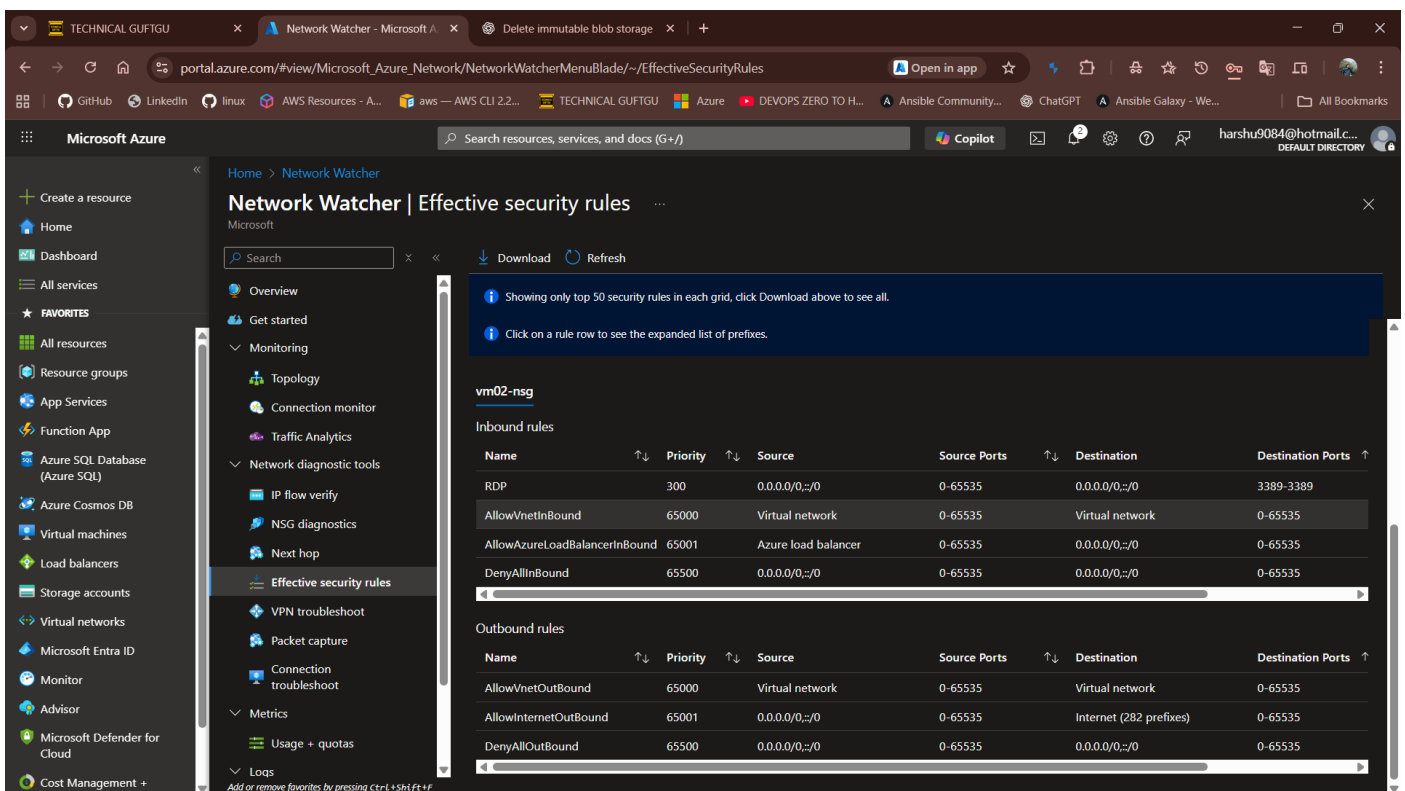

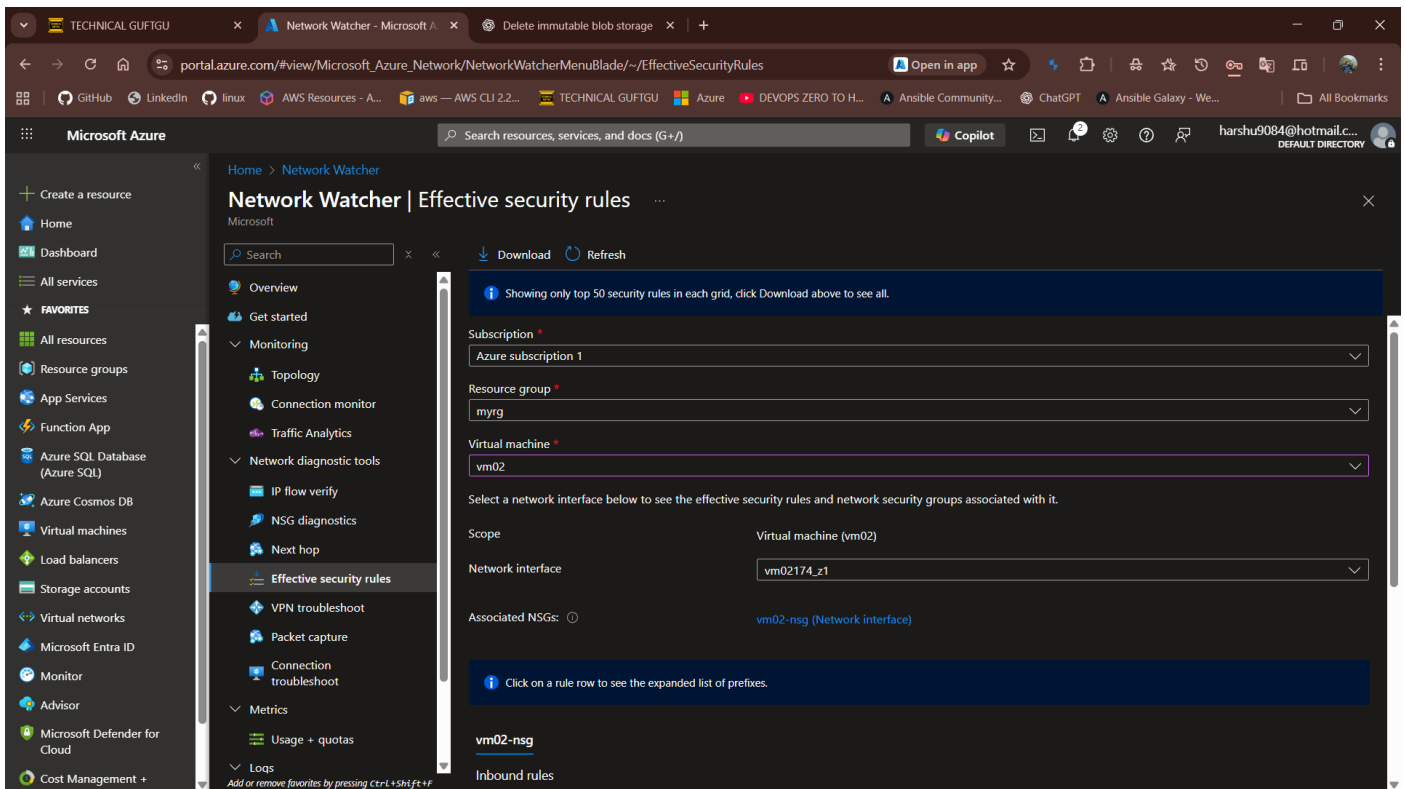

- Subnet NSG allows:
 - ✅ Port 80 (HTTP)
- VM NSG allows:
 - ✅ Port 22 (SSH)
 - ❌ Denies everything else

When Azure calculates the **effective rules** for that VM, it means:

The VM will allow only Port 80 and Port 22.

Everything else is blocked.

✅ **Effective Security Rules = Subnet rules + NIC rules (combined)**

- **What is Connection troubleshooting?**

Connection Troubleshoot in Azure helps you check if two resources can connect to each other — for example, if your VM can reach another VM, database, or website — and tells you where the connection fails if it does not work.

Network Watcher connection troubleshoot provides the capability to check a direct TCP or ICMP connection from a virtual machine (VM), application gateway v2, or Bastion host to a VM, fully qualified domain name (FQDN), URL, or IP address. To start, choose a source to start the connection from, and the destination you wish to connect to and select "Run diagnostic tests". [Learn more.](#)

The screenshot shows the Microsoft Azure Network Watcher Connection troubleshooter interface. The left sidebar contains navigation options like 'Home', 'Dashboard', 'All services', 'FAVORITES', 'All resources', 'Resource groups', 'App Services', 'Function App', 'Azure SQL Database (Azure SQL)', 'Azure Cosmos DB', 'Virtual machines', 'Load balancers', 'Storage accounts', 'Virtual networks', 'Microsoft Entra ID', 'Monitor', 'Advisor', 'Microsoft Defender for Cloud', and 'Cost Management +'. The main content area is titled 'Network Watcher | Connection troubleshoot'. It includes a search bar, a 'Run diagnostic tests' button, and a 'Results' section. The 'Results' section shows the test(s) ran: Connectivity, NSG diagnostic, Next hop, Port scanner. The source is 'vm01' and the destination is 'vm02'. There is an 'Export to CSV' button. Below this is a table of diagnostic tests:

Test	Status	Details
Connectivity test	Reachable	Probes sent: 13, probes failed: 12 Average latency (ms): 17, minimum latency (ms): 17, maximum latency (ms): 17
Outbound NSG diagnostic	Allow	Outbound communication to destination is allowed
Inbound NSG diagnostic	Allow	Inbound communication to destination is allowed
Next hop (from source)	Success	Next hop type: Virtual Network Route table: System Route
Source port accessible	Timeout	
Destination port accessible	Timeout	

💡 What It Does

You give Azure:

- A **source** (like a VM or network interface)
- A **destination** (like another VM, IP address, or URL)
- A **port number** (like 22 for SSH, 3389 for RDP, 443 for HTTPS)

Then Azure checks the entire path and tells you:

- ✅ If the connection **succeeds**
- ❌ If it **fails**, where it failed — for example:
- NSG rule blocked it
- Route table problem
- Firewall issue
- Destination unreachable
